Abstracts

Thermal evaporation is a well-known method for coating a thin layer in which the source material evaporates in a vacuum due to high temperature heating, which facilitates the vapor particles moving and directly reaching a substrate where these vapors again change to a solid state. In this method, a charge holding boat or resistive coil is used in the form of a powder or solid bar. In order to get the high melting points necessary for metals, the resistive boat/coil is exposed to a large direct current (DC), where the high vacuum (below 10^{-4} Pa) supports the evaporation of the metal and further carrying it to the substrate. This technique is specially applicable for material with low melting points. Thermal evaporation is also used to produce polymeric coatings. Thermal evaporation by resistive heating of polymers is limited by the low thermal conductivity of polymers. On the other hand, electron beam evaporation of organic materials is limited by the decomposition of the molecules. However, there are some applications where polymeric films have been grown successfully by thermal evaporation, such as PTFE and nylon in metal/polymer nanocomposite films.

The global Thermal Evaporation Vacuum Coating Machine market size was estimated at USD 340.25 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 6.85% during the forecast period.
