Report Overview

TIGIT Therapies refer to a novel class of immunotherapeutic treatments that specifically target the T cell immunoglobulin and ITIM domain (TIGIT) protein. This protein is expressed on certain immune cells, particularly T cells and natural killer (NK) cells, and plays a role in regulating immune responses. By inhibiting TIGIT, these therapies aim to enhance the ability of the immune system to recognize and attack cancer cells. The goal of TIGIT Therapies is to boost the anti-tumor immune response, potentially leading to more effective cancer treatments. These therapies are in various stages of research and development, with clinical trials investigating their safety and efficacy in treating different types of cancer. The development of TIGIT Therapies represents an innovative approach in the field of immuno-oncology, seeking to improve patient outcomes by harnessing the body's own immune system to combat disease.
