Report Overview

Transition alumina, also known as activated alumina, is a highly porous, granular form of aluminum oxide (Al_2O_3) produced through the thermal dehydration of aluminum hydroxides like gibbsite or bauxite. It exhibits a transitional phase between aluminum hydroxide and stable alpha alumina, characterized by its high surface area, thermal stability, and adsorption properties. This material is widely used as a desiccant, catalyst support, adsorbent for water purification, and in the petroleum refining industry for fluoride removal. Its unique properties, such as chemical inertness and mechanical strength, make it indispensable in applications requiring high-performance filtration, drying, or catalytic processes. The market for transition alumina is driven by demand from water treatment, oil & gas, and chemical manufacturing sectors, with growth further influenced by advancements in environmental regulations and industrial processes requiring efficient adsorbents.
