Report Overview

Transmission gratings are optical components designed to selectively transmit light based on its wavelength or frequency. They function by allowing specific wavelengths of light to pass through while reflecting or blocking others. These gratings are typically made from materials such as glass or plastic and are etched with a series of parallel, equally spaced lines or grooves. The spacing and depth of these lines determine the grating's ability to diffract light, which is crucial for applications in spectroscopy, laser systems, and optical communication. Transmission gratings can be found in various configurations, such as blazed gratings that optimize light transmission at specific angles, or holographic gratings that offer high efficiency and wavelength selectivity. They are widely used in scientific research, medical diagnostics, and industrial applications where precise control over light wavelengths is essential.
