Report Overview

A VoIP Media Gateway is a telecommunication networking device that performs translation between different technologies, protocols, and networks. Networks such as Public System Telephone Network (PSTN), Next Generation Networks (NGN), and Wireless Networks, can all be interconnected together using a VoIP Media Gateway. The primary function of VoIP Media Gateways is analog-to-digital conversion of voice and creation of voice IP packets. Today's telecommunication is not limited to audio, as it involves showing information in multiple media formats, thus, VoIP Media Gateway has been developed to integrate data, audio, video, and fax transmission through a single platform. VoIP is the abbreviation of Voice over Internet Protocol, an IP-based technology to facilitate voice calls. Simply put, it is communication carried out via the internet for audio calls and multimedia meetings. VoIP technology is a series of procedures of transcoding, encoding, compression, and packing. The basic path for the audio to reach the receiving end from the transmitting end is firstly the audio-to-electronic conversion, i.e., the sound wave from the transmitting end converted to the simulated electronic signals; then, the simulated electronic signals are converted to the digital signals through sampling and encoding before transmitting waves of compressed frames with IP addresses and control messages. Frames are packed in layers to generate IP packets that can be correctly delivered to the destinations amongst the vast network. When arriving at the destinations, IP packets are converted to simulated audio signals that can be broadcasted through speakers, receivers or earphones, via de-packing, code restoration, and lectro-acoustic conversion to facilitate the two-side voice calls.
