Report Overview

Wafer Frontside Metal Deposition is a critical process in semiconductor manufacturing, specifically within the photolithography and deposition stages. This process involves the application of a thin layer of metal onto the frontside (or active surface) of a silicon wafer. The metal layer, typically composed of materials such as aluminum, copper, or tungsten, serves as a conductive path for electrical signals within the integrated circuit. The deposition is achieved through various techniques, including physical vapor deposition (PVD), chemical vapor deposition (CVD), or electroplating. This step is essential for creating the interconnects and contact points that facilitate communication between the various components on the chip. The precision and uniformity of the metal deposition directly impact the performance, reliability, and yield of the final semiconductor product.
