Executive Summary

Quantum dots (QDs) comprise a new class of material that can be tuned to emit light very efficiently at precise red, green and blue wavelengths, thus creating an ideal light spectrum for LCDs. Picture quality, color fidelity and accuracy have been steadily getting better due to improved display technology, advanced signal processing, automated factory calibration, and increased competition. QD technology helps to close one of the major performance gaps between LCD and OLED displays: color. QD gives LCD displays a wider color gamut and better power efficiency. It is expected to be one of the biggest sea changes in the television market. The market estimation are made on the basis of some assumptions of the past years volume production and expected production in the future and projected price fluctuations. Quantum dot technology offers improved picture quality at a fraction of the price of organic light-emitting diodes (OLED).

The market for quantum dot technology is currently dominated by three commercial applications: quantum dot backlight filters, quantum dot color filters and quantum dot backlight units. Quantum dot is the emerging technology in the display market. Consumers are always in need of new technology which will give them an improved viewing experience. Quantum dot TV will result in enhanced color gamut and will observe quick penetration into the market after 2018. Continuous improvement of the quality of displays is a key demand of companies that market display based products. QD technology is particularly attractive as it allows absolute improvement in the quality of LCD displays so that they can compete with next generation OLED products.
