Research Summary

A bone-anchored hearing aid (BAHA) is a type of hearing device that helps individuals with hearing loss by utilizing bone conduction. It consists of three main components: a small titanium implant surgically placed in the skull bone behind the ear, an abutment that connects the implant to the external component, and the external sound processor that captures and processes sound. The sound processor, worn behind the ear, picks up sounds and converts them into vibrations. These vibrations are then transmitted through the implant and skull bone, directly stimulating the inner ear, bypassing any issues with the outer or middle ear. BAHA is particularly beneficial for individuals with conductive hearing loss, single-sided deafness, or those who cannot wear traditional hearing aids due to ear canal problems. It provides improved sound perception, localization, and overall hearing experience.
