Research Summary

Bone replacement refers to the process of replacing damaged or missing bone tissue with synthetic or biological materials to restore function, stability, and structural integrity. It is commonly performed in orthopedic and maxillofacial surgeries to address conditions such as bone fractures, defects, non-unions, or bone loss due to trauma, disease, or congenital abnormalities. Several techniques and materials can be used for bone replacement, including autografts (bone taken from the patient's own body), allografts (bone from a donor), xenografts (bone from another species), synthetic materials (such as ceramics or polymers), or a combination thereof. The goal of bone replacement is to facilitate the regeneration of new bone tissue, provide support for surrounding structures, and promote proper healing and functional recovery. The choice of bone replacement technique and material depends on factors such as the patient's condition, the extent of the bone defect, and the surgeon's expertise.
