Research Summary

Carbonized rice husk, also known as rice husk charcoal or rice husk biochar, is a carbon-rich material produced by heating rice husks in a low-oxygen environment, a process known as carbonization or pyrolysis. Rice husks are the outer layer of rice grains and are a byproduct of rice milling. During carbonization, rice husks are heated to high temperatures, typically between 400°C to 700°C, in the absence of oxygen. This causes the organic components of the rice husks to decompose, leaving behind a carbon-rich residue. Carbonized rice husk is porous and has a high surface area, making it useful in various applications such as soil improvement, water filtration, and as a component in renewable energy production. It can be used as a soil amendment to improve soil structure, moisture retention, and nutrient availability. Additionally, it is utilized in water treatment processes due to its ability to adsorb contaminants. Furthermore, carbonized rice husk can be used as a renewable source of energy through combustion or gasification, contributing to sustainable energy production.
