Research Summary

A central venous catheter (CVC) is a type of medical device that is inserted into a large central vein, such as the subclavian vein, jugular vein, or femoral vein, to provide access to the central venous system. It is used for various purposes, including the administration of medications, fluids, blood products, or parenteral nutrition, as well as for monitoring central venous pressure and obtaining blood samples. A CVC consists of a flexible catheter that is inserted through the skin into the chosen vein and advanced until the tip is positioned within the desired central vein. The catheter is typically tunneled under the skin to reduce the risk of infection and is attached to an external hub or port that allows for the administration or withdrawal of fluids. CVCs come in different sizes and types, such as single-lumen, double-lumen, or multi-lumen catheters, depending on the intended use. They are commonly used in critical care settings, surgery, and long-term medical treatments when peripheral venous access is challenging or not feasible. Proper care, sterile technique, and regular monitoring are crucial to prevent complications associated with CVCs, such as infection, thrombosis, or catheter-related bloodstream infections.
