### Research Summary

Cytology and HPV testing are two methods used in cervical cancer screening to detect abnormalities in cervical cells and identify the presence of human papillomavirus (HPV), a common sexually transmitted infection known to cause cervical cancer. Cytology, also known as the Pap test or Pap smear, involves collecting cells from the cervix and examining them under a microscope to identify any abnormal changes, such as precancerous or cancerous cells. HPV testing, on the other hand, detects the presence of high-risk HPV strains in cervical cells, which are associated with an increased risk of cervical cancer. The combination of cytology and HPV testing allows for more accurate and comprehensive screening, as it can detect both cellular abnormalities and the presence of HPV infection. This dual approach has greatly improved the effectiveness of cervical cancer screening programs, enabling early detection and treatment of precancerous lesions, ultimately reducing the incidence and mortality of cervical cancer.
