### Research Summary

Endobronchial Ultrasound (EBUS) biopsy is a minimally invasive medical procedure used to diagnose and evaluate lung conditions, particularly lung cancer and other pulmonary diseases. During the procedure, a flexible bronchoscope equipped with an ultrasound transducer at its tip is inserted through the patient's mouth or nose and guided down into the airways of the lungs. The ultrasound technology allows real-time imaging of the structures within and around the airways, enabling precise visualization of abnormalities, such as tumors or lymph nodes. EBUS-guided biopsies permit doctors to obtain tissue samples or aspirates from these areas for diagnostic purposes, aiding in the early detection and staging of lung diseases, and guiding treatment decisions, often avoiding the need for more invasive procedures like surgery. EBUS biopsy is considered a valuable tool in the diagnosis and management of lung conditions while minimizing patient discomfort and recovery time.
