### Research Summary

A gamma camera, also known as scintillation camera or Anger camera, is a medical imaging device used in nuclear medicine to detect gamma rays emitted by radioactive substances within the body. It consists of a large detector head containing numerous scintillation crystals coupled to photomultiplier tubes. When a gamma-emitting radiopharmaceutical is introduced into the patient's body, the emitted gamma rays interact with the scintillation crystals, producing flashes of light. These flashes are then converted into electrical signals by the photomultiplier tubes. The gamma camera's sophisticated electronics process and analyze these signals to create detailed images of the distribution of the radiopharmaceutical within the body. This imaging technique is valuable for diagnosing various medical conditions, such as detecting abnormalities in organs, tissues, or bones, and it plays a crucial role in nuclear medicine for both diagnostic and research purposes.
