Research Summary

A hard carbon anode precursor is a material used in the production of anodes for lithium-ion batteries. Hard carbon is a type of carbon material with a highly disordered structure, which allows it to store lithium ions efficiently during battery charging and discharging cycles. The precursor material undergoes a series of heat treatment processes, such as pyrolysis or carbonization, to convert it into hard carbon. During these processes, the precursor material undergoes structural transformations, resulting in the formation of a disordered carbon structure with a high surface area. This disordered structure enables the hard carbon anode to accommodate a large number of lithium ions, leading to high capacity and long cycle life in lithium-ion batteries. Hard carbon anode precursors are being extensively researched and developed for their potential to improve the energy density, performance, and stability of lithium-ion batteries, particularly in applications like electric vehicles and grid energy storage.
