Research Summary

Immunoturbidimetry reagents are biochemical substances used in immunological assays to measure the concentration of specific substances in biological samples based on the principle of turbidimetry. Turbidimetry involves the measurement of the degree of turbidity, or cloudiness, in a liquid sample caused by the presence of suspended particles. In immunoturbidimetry, antibodies are immobilized onto particles such as latex beads or polystyrene microparticles, forming immune complexes when they bind to target analytes in the sample. These immune complexes scatter light passing through the sample, causing a decrease in the intensity of transmitted light, which is measured by a photodetector. The degree of turbidity is proportional to the concentration of the target analyte in the sample, allowing for quantitative analysis. Immunoturbidimetry reagents typically include the antibody-coated particles, buffers, stabilizers, and other additives necessary to facilitate the formation of immune complexes and accurate measurement of turbidity. These reagents are widely used in clinical laboratories for assays such as measurement of proteins (e.g., C-reactive protein, immunoglobulins) and other analytes in serum or plasma samples for diagnostic and monitoring purposes.
