### Research Summary

Injectable bone graft refers to a type of bone grafting material that is in a liquid or semi-solid form, allowing it to be injected directly into the site where bone regeneration or augmentation is needed. These graft materials typically consist of a combination of biocompatible substances such as bone morphogenetic proteins (BMPs), calcium phosphate ceramics, collagen, or synthetic polymers, which promote bone healing and regeneration. Injectable bone grafts are commonly used in orthopedic and dental surgeries to fill bone defects, promote fusion in spinal surgeries, augment bone in dental implant procedures, and facilitate fracture healing. Their injectable nature offers several advantages over traditional bone grafting techniques, including minimally invasive delivery, precise placement into complex anatomical defects, reduced surgical morbidity, and enhanced patient comfort. Additionally, injectable bone grafts provide a scaffold for new bone formation and can stimulate the body's natural healing processes, ultimately leading to improved outcomes in bone repair and reconstruction.
