Research Summary

Intermittent catheters are medical devices used for the management of urinary retention or incontinence. These catheters are designed to be inserted into the bladder intermittently to empty urine and then removed. Unlike indwelling catheters that remain in the bladder for an extended period, intermittent catheters are single-use and are typically discarded after each use. They come in various lengths, materials, and designs to accommodate different patient needs and preferences. Intermittent catheterization is commonly used for individuals with conditions such as spinal cord injuries, neurogenic bladder dysfunction, or other urological issues. The procedure is performed under sterile conditions to reduce the risk of infection, and it allows individuals to maintain greater control over their bladder function while minimizing the risk of complications associated with long-term catheter use.
