Research Summary

An intramedullary nail, also known as an intramedullary rod or IM nail, is a surgical implant used in orthopedic procedures to treat fractures of long bones, particularly those in the femur and tibia. This device is designed to stabilize and align fractured bones internally. During the procedure, the intramedullary nail is inserted into the medullary canal of the affected bone, providing internal support and allowing for more rapid healing. The nail is typically made of materials like stainless steel or titanium and comes in various sizes to accommodate different anatomies. Intramedullary nailing is a common technique used in orthopedic surgery, as it offers advantages such as minimal soft tissue disruption, early mobilization, and reduced risk of infection compared to traditional external fixation methods. The intramedullary nail provides mechanical stability to the fractured bone, promoting optimal conditions for the healing process and allowing patients to regain function more effectively.
