Research Summary

A minimally invasive fascial closure device is a medical tool or device used in surgical procedures to securely close the fascial layer after a minimally invasive surgery. The fascia is a connective tissue layer that surrounds and supports organs and muscles. These closure devices are specifically designed to minimize tissue trauma and postoperative complications. They typically consist of a deployment mechanism that facilitates the placement of sutures or anchors through the fascial layer, ensuring a secure closure. The device helps reduce the risk of herniation or wound complications by providing a reliable and efficient method of closing the fascial layer with minimal disruption to the surrounding tissues. This type of device is commonly used in laparoscopic or robotic surgeries where the incisions are small and require precise closure techniques to promote optimal healing and recovery.
