Research Summary

A Network Packet Broker (NPB) is a device or software solution that provides visibility and control over network traffic by intelligently capturing, filtering, and distributing network packets. NPBs sit between network devices, such as switches and routers, and network monitoring tools, such as intrusion detection systems (IDS), network analyzers, or security information and event management (SIEM) systems. They collect data from various network links and then filter, aggregate, or modify the packet streams based on defined rules and policies. Network Packet Brokers can perform functions such as load balancing, deduplication, traffic filtering, packet slicing, protocol conversion, and time stamping. By centralizing and optimizing network traffic, NPBs enhance the efficiency and effectiveness of network security, monitoring, and analysis tools, allowing organizations to gain actionable insights, troubleshoot network issues, and detect and respond to security threats effectively. NPBs are especially valuable in large-scale and complex network environments, providing the necessary visibility and control for robust network management and security operations.
