Research Summary

Radiofrequency ablation (RFA) for pain management is a medical procedure that uses radiofrequency energy to target and disrupt the function of nerves causing chronic pain. It is often employed to alleviate pain associated with conditions such as arthritis, spinal joint degeneration, or certain nerve disorders. During the procedure, a specialized needle or electrode is guided to the targeted nerve or pain-sensitive tissue using fluoroscopic or ultrasound imaging. Once properly positioned, the radiofrequency energy heats the surrounding tissue, creating a lesion that disrupts the transmission of pain signals. RFA is considered a minimally invasive and relatively low-risk procedure, and its effects can provide pain relief for an extended period, ranging from months to years. This technique is particularly useful for individuals experiencing chronic pain who have not responded adequately to conservative treatments and may offer an alternative to surgical interventions. The specific application and success of RFA depend on the underlying cause and location of the pain being treated.
