Research Summary

Transcatheter Aortic Valve Replacement (TAVR) is a minimally invasive medical procedure used to treat aortic valve stenosis, a condition where the aortic valve narrows and restricts blood flow from the heart to the rest of the body. Unlike traditional open-heart surgery, TAVR is performed by threading a catheter through blood vessels, often starting in the leg, to reach the heart. Once in position, a replacement valve is deployed, pushing aside the diseased valve and restoring normal blood flow. TAVR is particularly beneficial for patients who may be at higher risk for complications with traditional surgery. The procedure has revolutionized the treatment of aortic valve stenosis, offering reduced recovery times, shorter hospital stays, and providing a viable option for those who were previously considered ineligible for surgery. However, the suitability of TAVR for an individual patient is determined based on various factors, and the decision is made in consultation with a heart care team.
