### Research Summary

A transdermal patch is a medical adhesive patch that delivers medication through the skin and into the bloodstream over a controlled period. These patches are designed to provide a convenient and non-invasive method of drug administration. The patch typically consists of multiple layers, including a backing layer, a drug reservoir or matrix, and an adhesive layer that adheres to the skin. The drug, often in the form of a gel or solid matrix, is released gradually, allowing for sustained and controlled delivery. Transdermal patches are used for a variety of medications, including pain relievers, hormone therapies, and nicotine replacement. They offer benefits such as improved patient compliance, reduced side effects, and the avoidance of the digestive system. The design and formulation of transdermal patches consider factors like skin permeability, drug release kinetics, and adhesion to ensure effective and safe drug delivery.
