Research Summary

Tumor ablation is a medical procedure aimed at destroying or eliminating abnormal tissue growth, commonly referred to as tumors. This technique is often used in the treatment of certain types of cancers, particularly when surgical removal may not be feasible or appropriate. Tumor ablation can be achieved through various methods, including radiofrequency ablation (RFA), microwave ablation, laser ablation, cryoablation, and high-intensity focused ultrasound (HIFU). These techniques involve the targeted application of heat, cold, or other forms of energy to the tumor, causing coagulative necrosis or cellular destruction. Tumor ablation is considered a minimally invasive alternative to surgery and may be suitable for patients with small tumors or those who are not good candidates for surgery due to underlying health conditions. It is often employed in the treatment of liver, kidney, lung, and prostate cancers, among others. The choice of ablation method depends on the type and location of the tumor and the patient's overall health.
