Research Summary

Urinary catheters are medical devices designed to assist in the drainage of urine from the bladder when a person is unable to do so naturally. These flexible tubes are inserted through the urethra into the bladder or, in some cases, directly through the abdominal wall into the bladder (suprapubic catheters). Urinary catheters are commonly used in various clinical situations, including post-surgery recovery, urinary retention, or when managing certain medical conditions. Indwelling catheters remain in place for an extended period, while intermittent catheters are used periodically for drainage. The choice of catheter type depends on the individual's medical needs and the specific situation. While urinary catheters serve essential medical purposes, they require careful management to prevent complications such as infections, and their usage is typically overseen by healthcare professionals.
