Abstracts

A landfill compaction vehicle has two main functions: to spread the waste evenly in layers over the landfill, and to compact waste to reduce its volume and help stabilize the landfill. Proper waste compacting includes the process of using a steel wheeled/drum landfill compactor to shred, tear and press together various items in the waste stream so they consume a minimal volume of landfill airspace. The higher the compaction rate, the more trash the landfill can receive and store. This will also reduce landslides, cave-ins and minimize the risk of explosions of landfill gas (see landfill gas migration).

Main compaction is produced by the landfill compactors steel tooth on the wheel drums. Special teeth can penetrate the waste and deliver a focused compression point, providing compaction and increased density. Ground pressure of the tooth can exceed over 4,000 pounds per square inch (28,000 kPa) (PSI). The design of the machine and more importantly the wheels and the teeth is very critical in compaction. Power transmission from engine to the wheel drums is another key factor in compactors, depending on the application and size of the landfill, machine size and configuration is selected, over size or single wheel drums or too many teeth will not result in higher compaction and longer landfill life.
