## Abstracts

According to our latest research, the global Electroless Ni-P Coating market size will reach USD million in 2031, growing at a CAGR of %over the analysis period.

Electroless nickel-phosphorus (Ni-P) coating consists of an alloy of nickel and phosphorus. The autocatalytic deposition process occurs in an aqueous solution with chemical reactions caused by the catalytic reduction of the nickel ion with sodium hypophosphite in acid baths. Electroless (Chemical) nickel plating is an autocatalytic reduction of nickel (precipitation), the catalyst being the base metal (Fe or Al) deposit nickel and phosphorus (NiP) alloy coating. The main difference between classic electrolytic nickel plating and chemical nickel plating is that the chemical nickel plating is done without the use of electricity, therefore without the use of anodes, as well as in the coating characteristics. Since no current is used, chemical nickel coatings are of equal thickness over the entire surface of the object (no unequal distribution of potentials along the edges), therefore, chemical nickel is suitable for objects of complicated geometry – cavities, pipes, holes, etc. The precipitated coating hardness of 550 HV (50-52 HRc) is much higher than the hardness of electrolytic nickel, and after thermal heat treatment, the hardness could be increased up to 1000 HV (67-70 HRc), similar to hard chromium, so the process can replace hard chromium in many cases – especially for small items.
