Abstracts

According to our (Global Info Research) latest study, the global 3-State Output Flip-Flop market size was valued at USD million in 2022 and is forecast to a readjusted size of USD million by 2029 with a CAGR of % during review period. The influence of COVID-19 and the Russia-Ukraine War were considered while estimating market sizes.

A 3-state output flip-flop (Tri-state buffer/flip-flop) is a special type of latch or flip-flop whose output port can be in one of three different states: high, low, or high impedance, often used for input/output (I/O) port control in digital circuits. The tri-state output flip-flop has three input ports: data (Data) input port D, enable (Enable) input port E and clock (Clock) input port C. When the enable port E is at a high level, the state of the tri-state output flip-flop is controlled by the data input port D and the clock input port C, and can output a high level or a low level. When the enable port E is at a low level, the output port of the tri-state output flip-flop is in a high-impedance state, which is equivalent to disconnecting the output port. At this time, the tri-state output flip-flop has no influence on the external circuit. The output port of a tri-state output flip-flop is usually implemented by a tri-state buffer (Tri-state buffer), which has a control port for controlling the output state of the buffer so that it can be in high level, low power One of the flat or high-impedance states. By controlling the control port of the buffer, the output state control of the tri-state output flip-flop can be realized. In digital circuits, tri-state output flip-flops are often used to control the input and output of the bus (Bus), which can realize the data transmission of multiple devices sharing a bus, and improve the scalability and reliability of the system. In addition, the tri-state output flip-flop can also be used to implement circuit functions such as multiplexer (Multiplexer) and level conversion.
