## Abstracts

The global Active Metal Self-ligating Brackets market size is expected to reach \$ 132 million by 2032, rising at a market growth of 5.0% CAGR during the forecast period (2026-2032).

Active metal self-ligating brackets are fixed orthodontic brackets made mainly from medical-grade stainless steel or metal alloys, equipped with an elastic clip or spring-locking mechanism. Once closed, the clip actively presses the archwire into the slot, improving torque expression, rotational control, root control, and three-dimensional tooth movement. They are commonly used in complex cases and finishing stages.

The upstream supply chain includes medical-grade stainless steel, 17-4PH stainless steel, cobalt-chromium alloys, nickel-titanium spring clips, precision elastic clips, welding materials, polishing consumables, surface-treatment chemicals, and medical packaging. Downstream demand comes mainly from orthodontic device brands, dental distributors, dental chains, dental hospitals, and orthodontic clinics. Compared with passive metal brackets, active systems require tighter control over clip elasticity, fatigue resistance, slot accuracy, and assembly stability.

In 2025, global active metal self-ligating brackets production reached approximately 650 k units, with an average global market price is \$140 per unit.

Global active metal self-ligating brackets are a high-control product category within fixed orthodontic appliances. They are typically made of stainless steel or other medical-grade metals and use an integrated elastic clip, spring mechanism or active locking structure to hold the archwire without conventional elastomeric or metal ligatures. Their active design means that the locking mechanism contacts the archwire and applies a certain level of pressure, helping seat the wire more firmly in the bracket slot and

improving torque expression, rotational control, three-dimensional tooth movement and finishing precision. Compared with passive metal self-ligating brackets, active metal systems do not simply pursue the lowest possible friction; instead, they balance reduced ligation complexity with stronger archwire control. Compared with ceramic self-ligating brackets, metal products offer advantages in strength, clip or slide durability, slot precision, wear resistance and cost control.

In terms of industry trends, active metal self-ligating brackets are developing toward stronger control, lower profile, reduced friction loss, higher clip durability, better comfort and stronger compatibility with digital orthodontic workflows. Early self-ligating brackets mainly emphasized fewer ligation steps and faster archwire changes, while current active metal products place greater emphasis on wire engagement, slot-size consistency, clip force retention, opening-and-closing durability, rounded bracket edges and stable clinical handling. Because the active clip can provide a certain degree of wire constraint across different archwire stages, these brackets are suitable for cases where clinicians want to combine workflow efficiency with better control, especially in rotational correction, torque expression, arch leveling and finishing. However, contact between the active clip and the archwire may increase friction during some sliding mechanics, so clinical selection usually depends on treatment objectives, archwire sequence and clinician preference rather than a simple assumption that active or passive systems are universally superior.

The main growth drivers come from three areas. First, demand for adolescent and adult fixed orthodontic treatment remains strong, while patients increasingly value comfort, appointment efficiency, hygiene convenience and treatment experience, making active metal self-ligating brackets an upgraded alternative to conventional metal brackets. Second, orthodontic practices and dental chains are placing greater emphasis on treatment efficiency and standardized workflows; self-ligating designs reduce ligation steps, shorten archwire-change time and lower chairside complexity. Third, advances in precision metal processing, micro elastic clips, surface treatment and digital orthodontic workflows are driving continued improvement in slot accuracy, clip life, torque control, friction optimization and case adaptability. Overall, active metal self-ligating brackets are not 'automatic correction' devices and should not be promoted as products that necessarily shorten treatment time; they are better understood as an important fixed-appliance format supporting higher efficiency, stronger control, durability, comfort and digital workflow integration.
