Abstracts

Allergic contact dermatitis (ACD) is a common inflammatory skin disorder and an alternative form of contact dermatitis. It is manifestation of allergic responses caused by the contact of an allergic substance such as, nickel, gold, chromium, mercaptobenzothiazole, formaldehyde and many more. The other form of contact dermatitis is irritant contact dermatitis (ICD). Symptoms of allergic contact dermatitis (ACDs) are similar to that of irritant contact dermatitis, which makes the diagnosis harder. The symptoms of allergic contact dermatitis include presence of the skin lesion or rashes at the exposure site. Depending on the allergen type, it may form blisters, papules, simple red spots, vesicles and rashes. The rash can drain, ooze or crust and also becomes raw, thickened or scaled. Allergic contact dermatitis (ACD) is caused as a result of two stages, first stage sensitize and primes the immune system for allergic responses and the second stage, triggers it. The diagnosis of allergic contact dermatitis includes physical examination and medical therapy. The precise diagnosis based on the symptoms and by rash appearance is very rare. The intermittent or chronic rashes that are not clarified by historical data and physical examination often requires further testing. A patch test (contact delayed hypersensitivity allergy test) is a normally used to detect the actual cause of allergic contact dermatitis.
