## Abstracts

According to our (Global Info Research) latest study, the global Androgen Receptor Antagonist market size was valued at USD million in 2022 and is forecast to a readjusted size of USD million by 2029 with a CAGR of % during review period. The influence of COVID-19 and the Russia-Ukraine War were considered while estimating market sizes.

Androgen receptor (AR) is an important target of prostate cancer drugs, and its structure plays an important guiding role in drug development. The androgen receptor consists of 4 structural domains and 8 exons, which are N-terminal binding domain (NTD, exon 1), DNA binding domain (DBD, exon 2-3), hinge region (HR, exon 4), C-terminal binding domain (LBD, exons 5-8), nuclear localization signal (NLS) is a dichotomous motif contained within exons 3 and 4. The LBD contains a buried hormone-binding pocket (HBP) and a transcriptional activation domain, AF2. AF2 plays an important role in the formation of homodimers, AF2 contains helices 3, 4, 5 and 12 (H3, H4, H5, H12), H12 can change position when ligand binds, when ligand binds to the binding pocket Upon binding, H12 folds back closer to the binding site, preventing ligand disengagement. Non-steroidal AR antagonists avoid the common hormone-like toxic side effects of steroidal AR antagonists, expand clinical applications, and are currently the most commonly used prostate cancer drugs in the United States.
