Abstracts

According to our (Global Info Research) latest study, the global Anhydrous Crystalline Glucose market size was valued at US\$ 1001 million in 2025 and is forecast to a readjusted size of US\$ 1223 million by 2032 with a CAGR of 2.8% during review period.

In 2025, global sales of anhydrous crystalline glucose reached 1,476,000 tons, with an average price of \$659 per ton.

Anhydrous crystalline glucose refers to α -D-glucose crystals ($C_6H_{12}O_6$, molecular weight 180.16) that are free of crystallization, obtained from starchy raw materials (mainly corn starch) through liquid saccharification, refining, and then crystallization by high-temperature evaporation ($>70^\circ C$) or spray drying. It has a moisture content $\leq 1.0\%$ (typically 0.1-0.5%), a melting point of $146-150^\circ C$, and significantly higher hygroscopicity than its monohydrate counterpart, making it particularly suitable for applications sensitive to moisture or requiring high-temperature processing.

Anhydrous crystalline glucose uses essentially the same raw materials as its monohydrate counterpart, primarily corn starch (accounting for 70-80% of the total cost). It can be prepared through direct high-temperature crystallization ($>70^\circ C$) or by converting monohydrate glucose into crystals. Excipients include α -amylase, saccharifying enzyme, activated carbon, and ion exchange resin. However, the production process is significantly more energy-intensive, requiring high-temperature evaporation crystallization ($70-80^\circ C$) or spray drying ($120-150^\circ C$) to remove all water of crystallization, resulting in a 20-30% increase in steam and electricity consumption compared to monohydrate. In terms of cost structure, due to the complex dehydration process and the stricter purity ($\geq 99.8\%$) and bacterial endotoxin control (
