According to our (Global Info Research) latest study, the global Antimony Catalysts for Polyester Production market size was valued at US\$ 660 million in 2025 and is forecast to a readjusted size of US\$ 877 million by 2032 with a CAGR of 4.2% during review period.

Antimony Catalysts for Polyester Production are antimony-based chemical catalysts used to promote transesterification, esterification, and polycondensation reactions in the production of PET resins and polyester materials. Major products include antimony trioxide, antimony acetate, antimony glycolate, and antimony-containing mixed catalyst systems. They are widely used in bottle-grade PET, fiber-grade PET, film-grade PET, sheets, engineering plastics, and copolyester production. Key upstream inputs include antimony concentrate, antimony metal, antimony trioxide, acetic acid, ethylene glycol, oxidants, solvents, packaging materials, refining equipment, reactors, drying equipment, and quality-control instruments. Major downstream customers include PET resin producers, polyester chip manufacturers, bottle-grade PET producers, polyester filament and staple fiber companies, polyester film producers, food packaging material manufacturers, and engineering plastic compounders. The global effective production capacity in 2025 is estimated at approximately 36,000 tonnes, with sales volume of about 24,860 tonnes and a weighted average ex-factory price of around USD 25,800 per tonne. The industry's overall gross margin is generally estimated at 24%-39%.

The global market for Antimony Catalysts for Polyester Production remains centered on antimony trioxide, antimony acetate, and antimony glycolate. These products have mature industrial use, strong customer acceptance, and a leading position in PET and polyester production. Antimony catalysts offer a balanced combination of

polycondensation efficiency, polyester color, thermal stability, cost control, and process compatibility, making them widely used in bottle-grade PET, fiber-grade PET, film-grade PET, and sheet production. Demand is mainly concentrated in China, India, Southeast Asia, and the Middle East, where polyester capacity is large, while Europe, the United States, and Japan focus more on high-purity, low-impurity, food-contact, and specialty polyester applications. In the near term, antimony catalysts are unlikely to be fully replaced, but the product mix is moving toward higher purity, more specialized grades, and lower residues.

Market growth is mainly supported by demand for polyester fibers, bottle-grade PET, polyester films, sheets, and engineering plastics. Food and beverage packaging, textiles, industrial yarn, packaging films, optical films, electrical insulation films, and modified PET remain important end-use areas for polyester materials, supporting stable consumption of antimony catalysts. Antimony glycolate is becoming an important segment because of its relatively high catalytic activity, fast reaction rate, and good compatibility with selected polyester processes. As Asia continues to maintain a large polyester production base, suppliers with stable antimony resources, scalable production capacity, and proven qualification with polyester customers will be better positioned to secure long-term orders.

From a technology perspective, antimony catalysts for polyester production will continue to develop toward higher purity, lower impurities, lower metal residues, stable particle size, better dispersion, and application-specific customization. Bottle-grade PET requires transparency, color control, acetaldehyde control, and food-contact compliance, while film-grade PET emphasizes impurity control, agglomerate reduction, thermal stability, and optical performance. Fiber-grade PET focuses more on spinning stability, batch consistency, and overall cost. Conventional antimony trioxide will remain widely used, while high-purity antimony trioxide and antimony glycolate are expected to gain a higher share. Some customers will also adopt low-antimony or mixed catalyst systems to reduce antimony residues and improve polyester quality while controlling costs.

Industry development is still affected by antimony price volatility, stricter environmental regulation, higher food-contact compliance requirements, long customer qualification cycles, and the penetration of alternative catalysts. Although antimony catalysts remain cost-effective and process-stable in mature polyester lines, concentrated antimony supply, price fluctuations, and trade policy changes can affect downstream procurement costs and inventory strategies. Polyester plants usually operate continuously, and catalyst changes may affect reaction speed, polymer color, molecular-weight

distribution, and downstream processing performance, making customers cautious when introducing new suppliers or new grades. Future competition will focus on resource security, high-purity antimony supply, scalable antimony glycolate production, environmental compliance, stable delivery, and polyester process service capability.
