The Attentional Set-Shifting (AST) test system is an experimental device used to evaluate the cognitive flexibility and executive ability of rodents. The system trains animals to identify positive cues associated with rewards in stimuli of different dimensions (such as smell, vision, touch, etc.) and establish corresponding strategies to find rewards. At the same time, it requires animals to adjust the learned strategies or establish new strategies when the relationship between rewards and cues changes, so as to detect the role of the animal's prefrontal cortex and its subcortical neural pathways in cognitive flexibility. The AST test system is an important model for studying the neural basis of cognitive flexibility and its disorders. It has a wide range of applications in neuroscience and behavioral research, and can provide experimental basis for the study of related neuropsychiatric diseases.
