Bathymetry survey sonar is a technology used to measure and map the depth of water bodies, such as oceans, lakes, and rivers. It provides information about the underwater topography, which is crucial for various applications including navigation, marine exploration, environmental studies, and resource management. The bathymetry survey sonar system typically consists of a sonar transducer, which emits sound waves into the water, and a receiver that detects the echoes produced when the sound waves bounce off the seafloor or other underwater objects. The time it takes for the echo to return to the receiver is used to calculate the depth of the water.
