According to our (Global Info Research) latest study, the global Biodegradable Materials for Vascular Stents market size was valued at USD million in 2022 and is forecast to a readjusted size of USD million by 2029 with a CAGR of % during review period.

Biodegradable materials have gained significant attention in the development of vascular stents. Vascular stents are medical devices used to support and maintain the patency of blood vessels. Here are some biodegradable materials that have been explored for vascular stent applications:

Poly(lactic acid) (PLA) and Poly(glycolic acid) (PGA): PLA and PGA are biodegradable polymers that have been widely investigated for use in vascular stents. These materials gradually degrade in the body over time, eliminating the need for long-term implant presence. However, pure PLA and PGA stents may have limitations in terms of mechanical strength and degradation rate, so they are often combined or modified with other materials.

Poly(lactic-co-glycolic acid) (PLGA): PLGA is a copolymer that combines the properties of PLA and PGA. It offers improved mechanical strength and controllable degradation rates. PLGA-based stents can be tailored to meet specific needs by adjusting the ratio of lactic acid to glycolic acid in the polymer composition.

Polycaprolactone (PCL): PCL is another biodegradable polymer that has been explored for vascular stents. It has a slower degradation rate compared to PLA, PGA, and PLGA, which makes it suitable for long-term support of diseased vessels. PCL-based stents are known for their flexibility and mechanical properties.

Magnesium alloys: Magnesium alloys have attracted attention as biodegradable materials for stents due to their biocompatibility and favorable mechanical properties. Magnesium stents gradually degrade in the body and are replaced by newly formed tissue over time. However, further research is needed to address issues such as controlling the degradation rate and managing the potential release of magnesium ions.
