## Abstracts

A monoclonal antibody is a type of protein made in the laboratory that can bind to substances in the body, including cancer cells. A monoclonal antibody is made so that it binds to only one substance to treat different types of cancer. There are several types of monoclonal antibodies that are being used to treat certain types of cancer. Laboratory production of monoclonal antibodies is produced from clones of only one cell which means that every monoclonal antibody produced by the cell is the same due to which they are called as biosimilar monoclonal antibodies. Each monoclonal antibody recognizes one particular protein. They work in different ways depending on the protein they are targeting, hence different monoclonal antibodies are required to be made to target different types of cancer.
