Abstracts

The global Blocked Isocyanate Prepolymers market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

The term "blocked" refers to the chemical modification of the isocyanate groups in the prepolymer to temporarily render them inactive or less reactive. This blocking process involves reacting the isocyanate groups with a blocking agent, such as a phenol or an active hydrogen compound, to form a stable urethane or urea linkage. The purpose of blocking the isocyanate groups in the prepolymer is to delay their reactivity until specific conditions are met, typically through the application of heat or the introduction of a suitable catalyst. When these conditions are triggered, the blocking agents are cleaved, and the isocyanate groups are "unblocked," allowing them to react with additional polyols or crosslinking agents to form the final polyurethane product. Blocked isocyanate prepolymers offer several advantages in polyurethane production: Improved safety: Blocking the isocyanate groups reduces the risk of premature reactions, making handling and storage of the prepolymer safer. Controlled reactivity: The blocking process allows for precise control over the reactivity of the isocyanate groups, enabling better processability and control of the curing or foaming process. Extended pot life: By blocking the isocyanate groups, the pot life or working time of the prepolymer is extended, providing more time for processing and application. Enhanced compatibility: Blocked isocyanate prepolymers exhibit improved compatibility with various polyols and other additives, allowing for the formulation of tailored polyurethane systems.

Blocked isocyanate prepolymers are specialized polymer compounds used in the production of polyurethane materials. They are typically formed by reacting polyols with excess isocyanate groups, resulting in the formation of a prepolymer containing unreacted isocyanate functionalities.
