## Abstracts

Bone screws, also known as bone fixation screws, are medical devices that support internal bone fixation during an orthopaedic surgical procedure. Bone screw system are most often used for internal fixation to hold bone fragments together or to affix an implant, e.g. plate, to the bone. The material used for bone screw system production is inert, thus these screws try not to cause any irritation or allergic reactions inside the body. A bone screw system can be used to compress a fracture surface, fix a plate to a bone or it may be used to place and fix an external fixator or internal fixator to a bone. A position bone screw system keeps two fragments together holding in position without compression.

Bone screw system is a highly efficient instrument for the fasciation of a bone fragments by interfragmentary compression, or for fixing a plate, nail, or fixator to the bone. It is traditionally manufactured with preferred two choices of stainless-steel and titanium but technological shifts in healthcare facilities have led to the development of biocomposite materials and more affordable bone screw system. There are ranges of products available in order of their use, e.g., pedicle bone screw system is meant for spinal fusion, compression bone screw system is generally used for foot and ankle procedure or any bone that needs to bear stress. Manufacturing of these bone screw systems are mainly done in bulk in order to avoid cost pressure and are manufactured with different characteristics and designs, which are applicable for different targets.
