According to our (Global Info Research) latest study, the global Brain Computer Interface Technology market size was valued at US\$ 580 million in 2025 and is forecast to a readjusted size of US\$ 1303 million by 2032 with a CAGR of 12.4% during review period.

A brain–computer interface (BCI), sometimes called a neural-control interface (NCI), mind-machine interface (MMI), direct neural interface (DNI), or brain–machine interface (BMI), is a direct communication pathway between an enhanced or wired brain and an external device.

Brain Computer Interface (BCI) Technology is a technology that acquires brain signals, analyzes them, and translates them into commands for a computer or external device, enabling direct interaction without relying on the normal output pathways of peripheral nerves and muscles.

Medical Applications: BCIs have the potential to revolutionize healthcare by enabling direct communication between the brain and external devices. They can assist individuals with disabilities, such as paralysis, ALS, and spinal cord injuries, to regain mobility and independence. **Neurological Disorders:** BCIs offer new avenues for treating and managing neurological disorders such as epilepsy, Parkinson's disease, and depression. They allow for precise monitoring and intervention within the brain. **Technical Complexity:** Developing BCIs that are reliable, accurate, and minimally invasive is a significant challenge. The brain is highly complex, and interpreting its signals accurately requires advanced signal processing and decoding algorithms. **Invasive vs. Non-Invasive:** Invasive BCIs, which require surgical implantation, can

provide high-quality signals but come with risks and limitations. Non-invasive BCIs, while safer, often provide lower signal quality.
