CAR-T (Chimeric Antigen Receptor T-cell) therapy is a cutting-edge immunotherapy for hematological cancers, involving the genetic modification of a patient's T cells to express synthetic receptors targeting specific antigens on cancer cells. These engineered T cells are expanded in the lab and reintroduced into the patient, where they can recognize and destroy cancerous cells with high specificity. Key features include its remarkable efficacy in treating certain blood cancers like B-cell lymphomas, leukemias, and multiple myeloma, particularly in patients with relapsed or refractory disease, and its potential for long-term remission. CAR-T therapy is primarily applied in advanced hematological malignancies and is being explored for broader indications through ongoing clinical trials. Despite its promise, challenges such as high cost, manufacturing complexity, and management of severe side effects like cytokine release syndrome (CRS) remain areas of active research.
