According to our (Global Info Research) latest study, the global Catecholamines Anorexiant Drug market size was valued at US$ 814 million in 2025 and is forecast to a readjusted size of US$ 1139 million by 2032 with a CAGR of 5.0% during review period.

Catecholamine anorexiant drugs are a class of appetite suppressants that function by increasing the levels of catecholamines—such as norepinephrine, dopamine, and serotonin—in the brain. These neurotransmitters play a critical role in regulating mood, energy levels, and appetite. By enhancing catecholamine activity, these drugs help to reduce hunger and food intake, thereby promoting weight loss. Phentermine and diethylpropion are well-known examples of catecholamine anorexiants. These medications stimulate the central nervous system, leading to appetite suppression and increased energy expenditure. While effective for short-term weight management, catecholamine anorexiants can cause side effects such as increased heart rate, elevated blood pressure, anxiety, insomnia, and potential for dependency. Consequently, they are typically prescribed for short-term use and under close medical supervision, particularly for individuals who have not achieved sufficient weight loss through diet and exercise alone.
