## Abstracts

According to our (Global Info Research) latest study, the global Cell Imagers market size was valued at USD 5964.8 million in 2023 and is forecast to a readjusted size of USD 8695 million by 2030 with a CAGR of 5.5% during review period.

Cell imaging is the study of examining cell structures through various devices such as microscopes to better understand cellular mechanisms to help diagnose diseases and discover drugs. There are several methods of cell imaging, which include fluorescence microscopy (FM), high content screening (HCS), in situ hybridization (ISH), confocal laser scanning microscopy (CLSM), immunofluorescence imaging (IFI), super-resolution microscopy (SRM), and automated imaging. Some critical factors such as the maintenance of healthy cells at the microscope stage and the establishment of a feasible environment that is ideal for cells and does not affect their functionalities need to be ensured during cell imaging.

One of the key drivers that will stimulate the growth of the market in the coming years is the increasing demand for high content screening techniques. Automated microscopy, multi-parameter image processing, and unique visualization tools are increasingly used in analytical methods such as high content screening (HCS) or high content analysis (HCA) to generate quantitative data from cells. HCS is used to analyze data such as the number of cells or shape of the cell to detect changes in the reporter genes. HCS methods are also used to measure the mitotic index, detect changes in the cell cycle, detect protein synthesis, and measure the amount of cell proliferation. The growing disease burden is increasing the need for personalized medicine that requires advanced techniques such as HCS. This in turn, will drive the demand for cell imaging solutions during the predicted period.
