Abstracts

According to our (Global Info Research) latest study, the global Chelated-Iron Agricultural Micronutrient market size was valued at USD million in 2023 and is forecast to a readjusted size of USD million by 2030 with a CAGR of % during review period.

Chelated micronutrients are produced by altering positively charged cat-ions to negatively charged molecules. As soil itself is negatively charged, it repels negatively charged molecules of chelated micronutrients, making it easily available for uptake by plants. Chelated iron micronutrient is mostly used in calcareous (high pH) soils and soils low in organic matter. High intensive farming and modern fertilizers have caused depletion of various micronutrients from the soil, which are essential for healthy plant growth. Iron deficiency in plants causes chlorosis due to poor chlorophyll synthesis and also affects lignin formation, energy transfer and nitrogen reduction and fixation in plants.

The world population is continuously increasing and the demand for quality food is increasing rapidly, especially in emerging markets as the purchasing power of buyers has grown significantly. Upgraded farming practices and government subsidies to waive the fertilizers price for farmers have generated a good demand for chelated iron micronutrient for crops like soybean, alfalfa and turf grass etc. Thus, the market for chelated iron micronutrient is expected to exhibit a robust growth in the coming years.
