Abstracts

Chromium is a kind of micro-band blue silver-white metal. Chromium is easily passivated in the air, and a very thin passivation film is formed on the surface to show the properties of precious metals.

SCOPE OF THE REPORT:

The chrome layer has a very high hardness, and the hardness can vary within a wide range of 400 to 1200 HV depending on the composition of the plating solution and the process conditions. The chrome plating layer has good heat resistance. When it is heated below 500 °C, the gloss and hardness of the chrome layer are not changed significantly. The temperature is greater than 500 °C to start oxidative discoloration, and the hardness above 700 °C begins to decrease. The chrome layer has a low coefficient of friction, especially the dry friction coefficient, which is the lowest of all metals. Therefore, the chrome layer has good wear resistance.

The chrome layer has good chemical stability and does not function in alkali, sulfide, nitric acid and most organic acids, but is soluble in hydrochloric acid (such as hydrochloric acid) and hot sulfuric acid. In the visible range, chromium has a reflectivity of about 65%, between silver (88%) and nickel (55%), and because chromium does not change color, it can maintain its reflective ability for a long time and is superior to silver and nickel.

The worldwide market for Chrome Plating is expected to grow at a CAGR of roughly xx% over the next five years, will reach xx million US\$ in 2023, from xx million US\$ in 2017, according to a new GIR (Global Info Research) study.
