Abstracts

Idiopathic myelofibrosis is a chronic myelo-proliferative disorder and characterized by abnormal mutation of stem cells. This abnormal mutation of stem cells and excessive production of platelets result in development of fibrous tissues within the bone-marrow. This factor would ultimately negatively affect on the development of white blood cells (WBCs), red blood cells (RBCs) and platelets. The condition of idiopathic myelofibrosis may ultimately lead to the risk of acute myelogenous leukemia. Risk of idiopathic myelofibrosis is more in geriatric population as compared to children and adult population. Patients may develop symptoms such as weakness, weight loss, night sweats, hypertension and others. Blood chemistry tests, bone marrow aspiration, molecular testing and biopsy are useful diagnostic tools to diagnose and detect chronic idiopathic myelofibrosis. Patients with idiopathic myelofibrosis are advised to take drugs like hydroxyurea, interferon alfa, androgens, prednisone and others in order to treat this disorder. In addition, stem cell transplant and splenectomy is performed by physicians in severe cases of chronic idiopathic myelofibrosis.
