Abstracts

The global Cochlear Assistive Devices market size is expected to reach \$ 3453.2 million by 2029, rising at a market growth of 7.8% CAGR during the forecast period (2023-2029).

A cochlear implant, an implanted hearing aid, is a treatment for the deaf or hard of hearing. It's a small electronic device that measures and processes sound and then stimulates the auditory nerve, allowing people who cannot hear to hear.

Its function is to make patients with severe deafness (deaf people) have a certain sound perception. Unlike other types of hearing aids, such as hearing aids, cochlear implants do not work by amplifying sound, but by applying pulses of electrical stimulation to the still-functioning auditory nerve inside the cochlea. Most cochlear implant devices consist of an implanted part and an external part. The external part consists of a microphone, a voice processor, and a signal transmitter for sending commands to the implanted part. The implant part consists of a signal receiving and decoding module, and a stimulating electrode array. Although the current cochlear implant technology cannot fully restore or reconstruct normal hearing, it can effectively help deaf people hear environmental sounds and understand spoken conversations under certain conditions.
