Abstracts

The global Continuous Passive Exercise Device for Lower Limbs market size is expected to reach \$ million by 2029, rising at a market growth of % CAGR during the forecast period (2023-2029).

The lower limb continuous passive motion device is a medical device, which is usually used for rehabilitation treatment of patients after lower limb joint surgery or fracture and other injuries. Driven by an electric motor, the device simulates the natural movement of the lower limbs of the human body through a series of continuous, repetitive passive movements. The patient can place the lower limbs in the device under safe conditions and perform passive joint movements. The exercise does not require active participation from the patient, making it an effective treatment modality for those who are unable to actively exercise due to surgery or injury. The continuous passive exercise machine for the lower limbs can help restore the patient's joint flexibility, muscle strength and blood circulation by providing appropriate mechanical stimulation. It can also reduce postoperative complications such as muscle atrophy and joint stiffness. Rehabilitation therapists usually formulate a specific treatment plan according to the patient's condition, and monitor and adjust the parameters of the equipment during the rehabilitation process to ensure that the patient obtains the best therapeutic effect.
