According to our (Global Info Research) latest study, the global Cross-Band Repeater market size was valued at US\$ 572 million in 2024 and is forecast to a readjusted size of USD 795 million by 2031 with a CAGR of 4.8% during review period.

A cross-band repeater is a special type of radio repeater whose core function is to receive signals from one frequency band and forward them to another frequency band. This design breaks the limitation that traditional repeaters only work within the same frequency band and realizes communication bridging between different frequency bands. The cross-band repeater receives signals from a certain frequency band (such as 145 MHz in the VHF band) through an antenna. After amplification, filtering and demodulation, the received signal is converted into a format suitable for forwarding. The processed signal is modulated to another frequency band (such as 435 MHz in the UHF band) and radiated through the transmitting antenna. Cross-band repeaters allow devices in different frequency bands to communicate with each other, expand the communication range, support multi-band device access, and build heterogeneous communication networks.
